

Table card

Your table works through three steps in about fifty minutes. A rapporteur writes; everyone decides. Use the printed maps on the table and these sheets. Nothing here is a validated result: it is a working draft produced in a workshop.

Open the tool on one laptop or tablet per table: or open *index.html* from the USB stick on your table. It works without internet. **Work in the 2D map**; the 3D view is for the projector.

- 1 Weight the suitability criteria** (12 minutes). Rate them as they matter in *your own* context, not in Colombia. In the tool: section 1. On paper: Sheet 1. First choose the most important criterion, then rate the others against it; then choose the least important and rate the others against it. The scale runs from 2 to 9; the value 1 is reserved for the Best and the Worst themselves.
- 2 Place conflict and governance** (16 minutes). In the tool: section 2. On paper: Sheet 2 and the maps. GENTE kept the two indices outside the score, as an interpretive layer. Decide as a table where they should go: interpretive layer, weighted criteria, veto threshold, or sequencing tiers. Apply your choice to the table of departments by hand and see who moves, who leaves, and who stays.
- 3 Record and export** (9 minutes). In the tool: section 3, then *Download HTML*. On paper: Sheet 3. Five short answers, one per section of a policy brief outline. This sheet is what your table hands in.

The question under everything

The conflict index measures armed and humanitarian conflict. In La Guajira, wind projects are shaped by consultation and territorial disputes that the index does not measure. So La Guajira leads the wind ranking with a low conflict score. That is not an error of the data; it is a question about what the indicator measures and for whom. **What would your own indicator miss?**

Reading the maps

Green is always the desirable end of the scale: high viability, or low conflict, or high governance. Grey departments have no data for that technology. Hatched departments have been excluded by a threshold. On the two index maps (NCI, NGI) the legend direction is reversed on purpose so that green stays desirable.

Rapporteur: type the table name in section 3. Export before closing the page: nothing is sent anywhere, so an unexported record is lost. On paper, write the table name on every sheet and hand in Sheet 3.

Sheet 1 • Criteria weights (Best–Worst Method)

Table: Technology: ☐ Onshore wind ☐ Utility-scale solar

- 1

Tick the **most important** criterion (Best) in column B. Tick the **least important** (Worst) in column W. They must differ.
- 2

In column a_{Bj} , rate how much more important the Best is than each other criterion, from 2 (slightly) to 9 (absolutely). Write 1 in the Best's own row.
- 3

In column a_{jW} , rate how much more important each criterion is than the Worst, 2 to 9. Write 1 in the Worst's own row. The Best-versus-Worst value must be the largest number on the sheet, and it is written once, in the Best's row of this column.

Criterion	B	W	a_{Bj}	a_{jW}	$1 / a_{Bj}$	Expert panel
Resource quality						0.491
Land-use compatibility						0.165
Socio-environmental sensitivity						0.123
Distance to settlements						0.111
Grid accessibility						0.110

Expert-panel weights shown are for onshore wind (n = 10). For solar they are: resource 0.444, land use 0.144, socio-environmental 0.145, settlements 0.126, grid 0.179.

Weights by hand (approximation)

Without the tool, use the consistent-case approximation: each weight is proportional to $1 / a_{Bj}$. Fill the column $1 / a_{Bj}$ (the Best's row is 1), add the column, and divide each value by the total. Write the result next to the expert weight and note where your table diverges most.

Sum of $1 / a_{Bj}$ = Largest divergence from the expert panel:

Consistency check by hand

For each criterion j other than Best and Worst, compute $CR_j = | a_{Bj} \times a_{jW} - a_{BW} | \div (a_{BW}^2 - a_{BW})$. The table is consistent if the largest CR_j is below the threshold for your a_{BW} :

a_{BW}	3	4	5	6	7	8	9
Threshold (5 criteria)	0.167	0.190	0.231	0.264	0.282	0.296	0.306

Thresholds from Liang, Brunelli and Rezaei (2020), *Omega* 96, 102175. The criterion with the largest CR_j is the judgement to revise first.

Sheet 2 • Place conflict and governance

Table: Technology: ☐ Onshore wind ☐ Utility-scale solar

Choose one placement and tick it. Then apply it to the table on the next page by hand, using the two empty columns.

	Placement	What it does	How to apply it by hand
☐	Interpretive layer	GENTE baseline. Ranked by viable area; the indices annotate but do not score.	Keep the ranking as printed. Read NCI and NGI as commentary.
☐	Weighted criteria	Conflict and governance enter the composite score.	Choose a governance weight w (e.g. 0.35). New score = $(1 - w) \times \text{Normalised} + w \times ((1 - \text{NCI}) \times 0.5 + \text{NGI} \times 0.5)$. Re-rank.
☐	Veto threshold	Departments beyond a threshold leave the ranking.	Set NCI_{max} (e.g. 0.08) and NGI_{min} (e.g. 0.15). Strike out every department with NCI above or NGI below. List the survivors.
☐	Sequencing tiers	All remain, ordered into three tiers.	Deploy: $\text{NCI} \leq 0.10$ and $\text{NGI} \geq 0.40$. Prepare: $\text{NCI} > 0.25$ or $\text{NGI} < 0.28$. Conditional: everything else. Mark D, C or P.

Thresholds or weight chosen:

Onshore wind — 12 departments with viable area

#	Department	Viable km ²	Share %	Normalised	NCI	NGI	Your score / tier		New rank
1	La Guajira	1,286	6.25	1.00	0.099	0.391			
2	Cesar	574	2.55	0.41	0.062	0.118			
3	Atlántico	62	1.86	0.30	0.028	0.162			
4	Boyacá	154	0.67	0.11	0.009	0.463			
5	Nariño	195	0.62	0.10	0.219	0.380			
6	Norte de Santander	83	0.38	0.06	0.249	0.665			
7	Cundinamarca	65	0.27	0.04	0.000	0.211			
8	Valle del Cauca	38	0.18	0.03	0.085	0.469			
9	Magdalena	35	0.15	0.02	0.071	0.420			
10	Huila	26	0.14	0.02	0.102	0.874			
11	Cauca	38	0.12	0.02	0.561	0.239			
12	Tolima	28	0.12	0.02	0.042	0.285			

Normalised = share divided by the leading department's share (La Guajira = 1). NCI: 0 = no conflict, 1 = maximum. NGI: 0 = weakest governance, 1 = strongest.

GENTE project (Gobernanza Energética y Territorio), developed by Universidad del Magdalena for the Agencia Nacional de Hidrocarburos under Contract 618 of 2025. Workshop: Engineering Governance for Just Energy Transitions, Global Centres Symposium 2026, Berlin. Table materials v2.1 — use only if the digital tool is unavailable.

Sheet 2 (continued) • Utility-scale solar — 10 departments

#	Department	Viable km²	Share %	Normalised	NCI	NGI	Your score / tier		New rank
1	Atlántico	2,429	73.04	1.00	0.028	0.162			
2	Cesar	8,244	36.64	0.50	0.062	0.118			
3	Sucre	3,700	34.95	0.48	0.071	0.432			
4	La Guajira	5,082	24.70	0.34	0.099	0.391			
5	Córdoba	5,617	22.39	0.31	0.066	0.582			
6	Bolívar	5,600	21.01	0.29	0.059	0.266			
7	Santander	5,654	18.58	0.25	0.016	0.255			
8	Tolima	4,240	17.57	0.24	0.042	0.285			
9	Magdalena	3,575	15.47	0.21	0.071	0.420			
10	Antioquia	5,688	9.06	0.12	0.077	0.670			

Normalised = share divided by the leading department's share (Atlántico = 1).

What moved?

Departments that left or fell

Departments that rose or entered a better tier

What does your indicator not capture?

Sheet 3 • Annotated decision framework (table record)

Table: Context (sector, country, institution):

Technology: ☐ wind ☐ solar Placement: ☐ interpretive ☐ weighted ☐ veto ☐ tiers Thresholds / weight:

The five sections below follow the structure of the GENTE policy brief. One or two sentences each is enough.

1 • Problem

State the siting decision you face in your own context, in one sentence.

2 • Strategic finding

What did the ranking and the map reveal that a technical assessment alone would not?

3 • Critical risk

What does the conflict or governance indicator not capture in your context?

4 • Policy implication

Where would you place conflict and governance in the model, and who should decide that?

5 • Priority recommendation

One action, one responsible actor, one time horizon.
